A. The evaluation gap: published detectors are tested on the designs they were trained on

reported: 96 to 100 % accurate

on a design not in training: 51 to 71 % (IDNet), about half of alterations missed (FantasyID)

B. This study tests on a design, a dataset and a script the detector has never seen

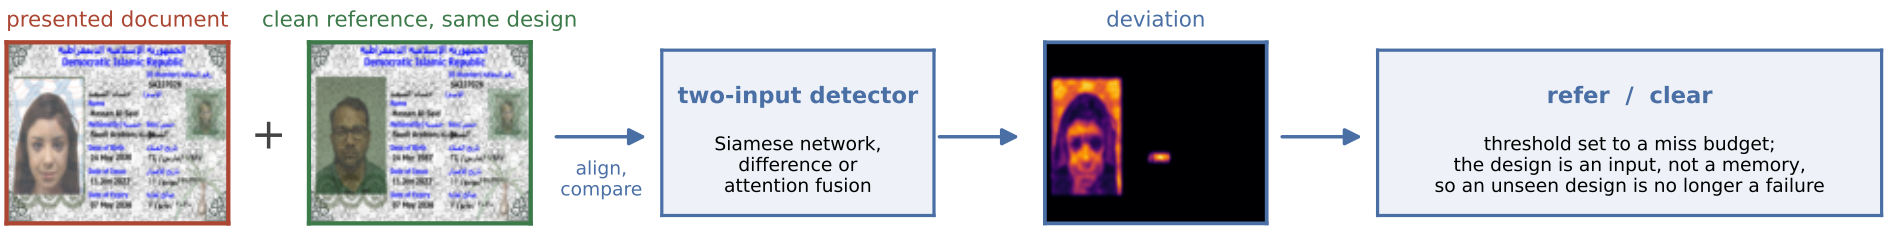

IDNet, SIDTD, FantasyID: 40 designs, 6 alteration types

Arabic design, altered portrait and birth year

A plain detector sees only this image.

It has never seen the design, so it cannot tell the design's own features from an alteration.

C. The method: give the detector the clean reference of the same design, and score the deviation

from the reader

retrieved from the 80-country template library the centre already holds

where the presented page departs from its design

D. What is reported, in the second line's own terms

plain vs reference-conditioned	referrals and misses	the gap between protocols	today's base rate
on every unseen level: does the reference close the gap?	share referred at 1 % and 5 % missed, against referring all	unseen design within dataset vs unseen dataset and script	20,307 referred, 902 altered (4.4 %)
